ABSTRACT

An optical wavelength control system for an optical source (LD) such as a laser diode in a DWDM transmitter module includes a beamsplitter arrangement (9, 10; 12) for propagating radiation from the source (LD) over two paths. A first (1) and a second (2) photodetector are each in a respective one of propagation paths, while a wavelength selective optical 10 filter (3) is interposed in the propagation path from the source (LD) to the first photodetector (1). (1) and second (2) photodetectors are thus adapted to generate photocurrents indicative of the possible displacement of the actual wavelength of the 15 radiation from said source (LD) with respect to a reference wavelength and the power emitted by the optical source, respectively. The beamsplitter 10; arrangement (9, 12) is arranged to split from said towards radiation source (LD) 20 photodetectors (1, 2) direction in generally transverse to said radiation the and wavelength selective optical filter (3) is mounted over beamsplitter arrangement (9, 10; 12) whereby beamsplitter arrangement, the optical filter (3) 25 the photodiodes (1, 2) comprise a compact assembly extending in a direction generally transverse to the propagation direction of the radiation from said source The optical beams lie in a plane that perpendicular to the optical bench plane, thus leading 30 to a significant footprint reduction.
